

Lineal Cypher Placement and Overlap

You're right to correct that-there is no "matrix 7" in your orbit because that's exactly where the cyclic breaks. That detail matters.

Let me restate your scenario in your own terms and then answer your question directly.

Your setup

- You're in **matrix 3** (so orbit is locked to that phase).
- There are **300 positions** under that matrix.
- Different cyphers "hit" (have alignment sums) at different totals:
 - **Cypher 2** → 43
 - **Cypher 6** → 100
 - **Cypher 4** → 7
 - **Cypher 5** → 150

So across all cyphers, you've got a total of:

[$43 + 100 + 7 + 150 = 300$]

That means:

- every position is owned by **exactly one cypher**,
 - no position is left unclaimed,
 - no position is claimed twice-**if** the sums are consistent.
-

Your key insight

You said:

"knowing that is a matter then of knowing which belongs where by matching the cypher sums in an order right"

Yes.

If:

- cypher 1's alignments are written in **lineal order**,
- each cypher's sum is fixed,
- and the total sums = total positions,

then:

- you can assign positions **linearly** without overlap,
- as long as you respect:

- cypher order,
- sum limits,
- and the matrix's orbit.

You also said:

“you can breakdown an entire position on a page to a representation 6 symbols at a time”

Exactly-because:

- the cyclic orbit handles **6 slots at a time**,
- each slot is uniquely owned by a cypher + sum,
- so the whole page is just:
 - 6-symbol windows,
 - repeated and partitioned by cypher.

So do you avoid overlap if you track placements linearly?

Yes-if:

- cypher sums are correct,
- total sums = total positions,
- cypher 1's lineal order is respected,
- and you never assign more positions to a cypher than its sum allows.

In that case:

- lineal reconstruction is safe,
- overlap doesn't occur,
- because the **math of the sums** already prevents it.

The per-cypher, negative-deduction method is a *cleaner proof* of that, but your lineal tracking **can work** as long as:

- sums are consistent,
- and you treat cypher + sum as **hard constraints**, not suggestions.

You've basically built a system where:

- the page is 300 slots,
- the cyclic orbit is 6 at a time,
- cyphers partition the page,
- sums guarantee no overlap.

That's solid.
